Eco 5316 Time Series Econometrics Lecture 24 State Space Models

Motivation

- time series models in economics and finance may often be represented in state space form
- state space model consists of a measurement equation relating the observed time series y_t to an unobserved state vector s_t and a state transition equation that describes the evolution of the state vector s_t over time
- state-space model provides a flexible approach to time series analysis, simplifying maximum-likelihood estimation and handling of missing values

ightharpoonup consider time series y_t satisfying

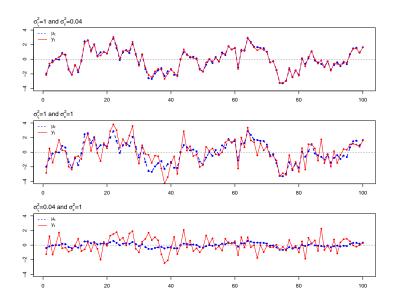

$$y_t = \mu_t + \varepsilon_t \quad \varepsilon_t \sim N(0, \sigma_{\varepsilon}^2)$$
$$\mu_{t+1} = \mu_t + \zeta_t \quad \zeta_t \sim N(0, \sigma_{\varepsilon}^2)$$

where $E(\varepsilon_t\zeta_t)=0$ and μ_1 is either known or drawn from known distribution

- lacktriangle here μ_t is an unobserved random walk, only y_t is observable, with noise $arepsilon_t$
- the simple model above could be used to model either log of an asset price, log of its volatility, detrended log of national income, detrended log of labor productivity . . .
- ▶ this model is an example of a linear Gaussian state space model

note that in the local level model

- since $y_t = \sum_{j=1}^t \zeta_j + \varepsilon_t$ innovations ζ_t have a permanent effect on y_t , but innovations ε_t have only a temporary effect on y_t
- lacksquare if $\sigma_{arepsilon}^2=0$ then y_t follows a pure random walk
- lacktriangle if $\sigma_\zeta^2=0$ then y_t fluctuates around constant mean μ_1

note that the Local Level Model implies that

$$y_{t+1} = y_t + \varepsilon_{t+1} - \varepsilon_t + \zeta_t$$

and so

$$Var(\Delta y_t) = 2\sigma_{arepsilon}^2 + \sigma_{\zeta}^2$$
 $cov(\Delta y_t, \Delta y_{t-1}) = -\sigma_{arepsilon}^2$ $cov(\Delta y_t, \Delta y_{t-j}) = 0$ for $j > 1$

• the above implies that y_t follows an ARIMA(0,1,1) model

$$y_t = y_{t-1} + a_t + \theta_1 a_{t-1}$$

since

$$Var(\Delta y_t) = (1+ heta_1^2)\sigma_a^2$$
 $cov(\Delta y_t, \Delta y_{t-1}) = heta_1\sigma_a^2$ $cov(\Delta y_t, \Delta y_{t-j}) = 0$ for $j > 1$

and by setting θ_1 to the solution of $1+\theta_1^2-\theta_1(2+\sigma_\zeta^2/\sigma_\varepsilon^2)=0$ we obtain exactly the above variance and covariances

Preview: Filtering, Prediction, Smoothing

- suppose that we have information $F_t = \{y_1, \dots, y_t\}$
- if parameters σ_{ε} , σ_{ζ} of the Local Level Model are known, the statistical inference we are interested in entails the following:
- **b** filtering: recovering μ_t and removing measurement error ε_t
- **prediction**: forecasting μ_{t+h} and y_{t+h} for h > 0
- ▶ **smoothing**: recovering μ_j for j < t

Preview: Filtering, Prediction, Smoothing

notation

- lacksquare $\mu_{t|j} = E(\mu_t|F_j)$ is the conditional mean of μ_t given F_j
- $\Sigma_{t|j} = Var(\mu_t|F_j)$ is the conditional variance of μ_t given F_j
- $y_{t|j} = E(y_t|F_j)$ is the conditional mean of y_t given F_j
- \triangleright $v_t = y_t y_{t|t-1}$ is the one step ahead forecast error
- $V_t = Var(v_t|F_{t-1})$ is the variance of the one step ahead forecast error

for the Local Level Model we have

▶ one step ahead forecast

$$y_{t|t-1} = E(y_t|F_{t-1}) = E(\mu_t + \varepsilon_t|F_{t-1}) = \mu_{t|t-1}$$

one step ahead forecast error

$$v_t = y_t - y_{t|t-1} = y_t - \mu_{t|t-1}$$

variance of the one step ahead forecast error

$$V_{t} = Var(v_{t}|F_{t-1}) = Var(y_{t}-y_{t|t-1}|F_{t-1}) = Var(y_{t}-\mu_{t|t-1}|F_{t-1})$$

$$= Var(\mu_{t}+\varepsilon_{t}-\mu_{t|t-1}|F_{t-1}) = Var(\mu_{t}-\mu_{t|t-1}|F_{t-1}) + Var(\varepsilon_{t}|F_{t-1})$$

$$= \Sigma_{t|t-1} + \sigma_{\varepsilon}^{2}$$

Kalman Filter for Local Level Model

- goal of Kalman filter is to obtain one step ahead predictions by updating the current estimate of state variable when new data point becomes available
- since innovations ε_t and ζ_t are Gaussian the joint distribution of $(\mu_t, v_t)'$ given F_{t-1} is also Gaussian

$$\begin{bmatrix} \boldsymbol{\mu}_t \\ \boldsymbol{v}_t \end{bmatrix}_{F_{t-1}} \sim N \left(\begin{bmatrix} \boldsymbol{\mu}_{t|t-1} \\ \boldsymbol{0} \end{bmatrix}, \begin{bmatrix} \boldsymbol{\Sigma}_{t|t-1} & \boldsymbol{\Sigma}_{t|t-1} \\ \boldsymbol{\Sigma}_{t|t-1} & \boldsymbol{V}_t \end{bmatrix} \right)$$

▶ conditional distribution of μ_t given F_t is thus $N(\mu_{t|t}, \Sigma_{t|t})$ where

$$\mu_{t|t} = \mu_{t|t-1} + K_t v_t$$

$$\Sigma_{t|t} = \Sigma_{t|t-1} (1 - K_t)$$

with $K_t = \sum_{t|t-1}/V_t$

▶ finally, given $\mu_{t|t}$ and $\Sigma_{t|t}$ the conditional mean and variance for period t+1 state are

$$\mu_{t+1|t} = E(\mu_t + \zeta_t | F_t) = E(\mu_t | F_t) = \mu_{t|t}$$

$$\Sigma_{t+1|t} = Var(\mu_{t+1} | F_t) = Var(\mu_t | F_t) + Var(\zeta_t) = \Sigma_{t|t} + \sigma_{\zeta}^2$$

Kalman Filter for Local Level Model

summary of Kalman Filter procedure for local level model:

- \blacktriangleright parameters σ_{ε}^2 and σ_{ζ}^2 are given
- ▶ initial state μ_1 is assumed to be distributed as $N(\mu_{1|0}, \Sigma_{1|0})$
- ▶ suppose that in period t given previous information F_{t-1} we have conditional mean $\mu_{t|t-1}$ and conditional variance $\Sigma_{t|t-1}$
- ▶ after observing y_t we have F_t and obtain conditional mean $\mu_{t+1|t}$ and conditional variance $\Sigma_{t+1|t}$ using

$$\begin{aligned} v_t &= y_t - \mu_{t|t-1} \\ V_t &= \Sigma_{t|t-1} + \sigma_{\varepsilon}^2 \\ K_t &= \Sigma_{t|t-1} / V_t \\ \mu_{t+1|t} &= \mu_{t|t-1} + K_t v_t \\ \Sigma_{t+1|t} &= \Sigma_{t|t-1} (1 - K_t) + \sigma_{\zeta}^2 \end{aligned}$$

 K_t is called Kalman gain; note that $K_t = \frac{\Sigma_{t|t-1}}{\Sigma_{t|t-1} + \sigma_{\varepsilon}^2}$, thus if the variance of temporary disturbance ε_t is large then K_t is small and even a large forecasting error leads to only a small update from $\mu_{t|t-1}$ to $\mu_{t|t}$

Kalman Filter for Local Level Model - Nile Data

see https://cran.r-project.org/web/packages/KFAS/vignettes/KFAS.pdf for details and examples how to define, estimate and simulate state-space models using KFAS package

```
library(magrittr)
library(KFAS)
v.ts <- datasets::Nile
# specify the state-space local level model
v.LLM <- SSModel(v.ts ~ SSMtrend(degree = 1, Q = list(NA)) , H = NA)
# maximum likelihood estimation of paramaters of Q and H (i.e. variances of the two inovations)
v.LLM.ML <- fitSSM(inits = log(rep(var(v.ts)/1000, 2)), model = v.LLM, method = "BFGS")
# run Kalman Filter and Smoother with estimated parameters
v.LLM.KFS <- KFS(v.LLM.ML$model)
# construct 90% confidence interval for filtered state
v.KF <- predict(v.LLM.ML$model, interval = "confidence", level = 0.9, filtered = TRUE)
v.KF[1,] \leftarrow NA
par(mfrow = c(2.2), cex = 0.8)
cbind(y.ts, y.KF) %>%
    plot.ts(plot.type = "single", col = c(1,4,4,4), lwd = c(1,2,1,1), lty = c(1,1,2,2))
legend("topright", legend = c("data", "filtered state", "90% confidence interval"),
       col = c(1,4,4), lty = c(1,1,2,2), lwd = c(1,2,1,1), bty = "n", cex=0.9)
c(v.LLM.KFS$v[-1]) \%\% ts(start = 1871) \%\%
    plot(main = expression(paste("forecast error ", v["t"])))
abline(h=0.col="grev")
c(v.LLM.KFS$P)[-1] \%\% ts(start = 1871) \%\%
    plot(main = expression(paste("variance of state ", Sigma["t|t-1"])))
c(v.LLM.KFS$F)[-1] %>% ts(start = 1871) %>%
    plot(main = expression(paste("variance of forecast error ", V["t"])))
```

Kalman Filter for Local Level Model - Nile Data

Kalman Smoothing for Local Level Model

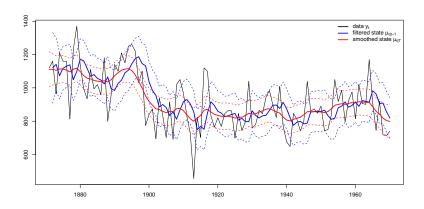

- ▶ smoothing is essentially a backward estimation of $\{\mu_1, \dots, \mu_T\}$ given the information set $F_T = \{y_1, \dots, y_T\}$
- ▶ the objective is thus to obtain conditional distributions $N(\mu_{t|T}, \Sigma_{t|T})$ for t = T-1, T-2, ..., 1 the procedure is going backward
- $ightharpoonup \mu_{t|T}$ is called smoothed state and $\Sigma_{t|T}$ smoothed state variance
- ▶ applying the properties of the conditional normal distribution one can derive the following backward recursive algorithm to compute smoothed state variables: using initial value $q_T=0$ and $M_T=0$ calculate for $t=T,\ldots,1$

$$\begin{aligned} q_{t-1} &= V_t^{-1} v_t + (1 - K_t) q_t \\ \mu_{t|T} &= \mu_{t|t-1} + \Sigma_{t|t-1} q_{t-1} \\ M_{t-1} &= V_t^{-1} + (1 - K_t)^2 M_t \\ \Sigma_{t|T} &= \Sigma_{t|t-1} + \Sigma_{t|t-1}^2 M_{t-1} \end{aligned}$$

Kalman Filtering and Smoothing for Local Level Model - Nile Data

Kalman Filtering and Smoothing for Local Level Model - Nile Data note that

- smoothed state variable $\mu_{t|T}$ is smoother then filtered state variable $\mu_{t|t-1}$
- confidence intervals for the smoothed state variables are also narrower than those of the filtered state variables

Local Linear Trend Model

consider time series y_t satisfying

$$y_t = \mu_t + \varepsilon_t \qquad \varepsilon_t \sim N(0, \sigma_{\varepsilon}^2)$$

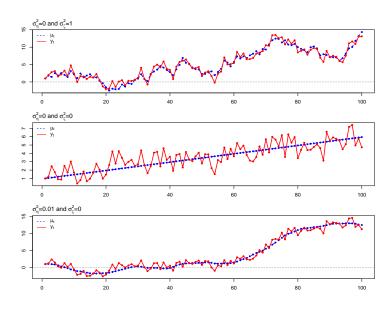

$$\mu_{t+1} = \beta_t + \mu_t + \zeta_t \qquad \zeta_t \sim N(0, \sigma_{\zeta}^2)$$

$$\beta_{t+1} = \beta_t + \eta_t \qquad \eta_t \sim N(0, \sigma_{\eta}^2)$$

where ε_t , ζ_t , η_t are independent at all lags and leads, and μ_1 , β_1 are either known or from known distribution

- if $\sigma_{\eta}^2 = 0$, $\sigma_{\zeta}^2 > 0$ then y_t is random walk with drift β_1
- if $\sigma_{\eta}^2=0$, $\sigma_{\zeta}^2=0$ then y_t fluctuates around a linear trend with slope β_1 and intercept μ_1
- lacktriangle if $\sigma_{\eta}^2>0$, $\sigma_{\zeta}^2=0$ then y_t fluctuates around a non-linear trend

Local Linear Trend Model

Linear Gaussian State Space Model

- local level and local linear trend models are particular cases of linear Gaussian state space model
- ▶ linear Gaussian state space model implemented in KFAS package

$$egin{aligned} oldsymbol{y}_t &= oldsymbol{Z}_t oldsymbol{s}_t + eta_t oldsymbol{s}_t + oldsymbol{s}_t + oldsymbol{S}_t oldsymbol{h}_t & oldsymbol{\sigma}_t \sim oldsymbol{\mathcal{N}}(oldsymbol{0}, oldsymbol{\mathcal{H}}_t) \ oldsymbol{s}_t &= oldsymbol{T}_t oldsymbol{s}_t \setminus oldsymbol{N}(oldsymbol{0}, oldsymbol{\mathcal{H}}_t) \ oldsymbol{s}_t &= oldsymbol{N}(oldsymbol{0}, oldsymbol{N}_t) \ oldsymbol{s}_t &= oldsymbol{S}_t \ oldsymbol{$$

where

 \mathbf{y}_t is an $k \times 1$ vector of observations

 \boldsymbol{s}_t is an $m \times 1$ state vector

 \boldsymbol{T}_t is an $m \times m$ matrix

 \mathbf{R}_t is an $m \times n$ matrix

 \mathbf{Z}_t is an $k \times m$ matrix

 ${oldsymbol{\eta}}_t$ is an $n{ imes}1$ vector

 ε_t is an $k \times 1$ vector

with initial state $s_1 \sim N(\mu_{1|0}, \mathbf{\Sigma}_{1|0})$ and $E(\varepsilon_t \eta_t') = \mathbf{0}$ so innovations in state transition equation and measurement equation are independent

- **>** system matrices T_t , R_t , Z_t , Q_t and H_t can be functions of some parameters θ that are estimated
- ▶ in many cases system matrices are actually time invariant

Linear Gaussian State Space Model

lacktriangle Kalman Filter algorithm, given initial values $oldsymbol{\mu}_{1|0}$ and $oldsymbol{\Sigma}_{1|0}$

$$egin{aligned} oldsymbol{v}_t &= oldsymbol{y}_t - oldsymbol{Z}_t oldsymbol{s}_{t|t-1} \ oldsymbol{V}_t &= oldsymbol{Z}_t oldsymbol{\Sigma}_{t|t-1} oldsymbol{Z}_t' + oldsymbol{H}_t \ oldsymbol{K}_t &= oldsymbol{T}_t oldsymbol{\Sigma}_{t|t-1} + oldsymbol{Z}_t' oldsymbol{V}_t^{-1} \ oldsymbol{s}_{t+1|t} &= oldsymbol{T}_t oldsymbol{S}_{t|t-1} + oldsymbol{K}_t oldsymbol{v}_t \ oldsymbol{\Sigma}_{t+1|t} &= oldsymbol{T}_t oldsymbol{\Sigma}_{t|t-1} (oldsymbol{T}_t - oldsymbol{K}_t oldsymbol{Z}_t)' + oldsymbol{R}_t oldsymbol{Q}_t oldsymbol{R}_t' \ oldsymbol{S}_t' + oldsymbol{N}_t oldsymbol{Q}_t' oldsymbol{N}_t' oldsymbol{S}_t' + oldsymbol{N}_t oldsymbol{Q}_t' oldsymbol{N}_t' \ oldsymbol{N}_t' oldsymb$$

this can be collapsed into two equations

$$\begin{split} s_{t+1|t} &= T_t s_{t|t-1} + T_t \mathbf{\Sigma}_{t|t-1} Z_t' \big(Z_t \mathbf{\Sigma}_{t|t-1} Z_t' + H_t \big)^{-1} \big(y_t - Z_t s_{t|t-1} \big) \\ \mathbf{\Sigma}_{t+1|t} &= T_t \mathbf{\Sigma}_{t|t-1} T_t' - T_t \mathbf{\Sigma}_{t|t-1} Z_t' \big(Z_t \mathbf{\Sigma}_{t|t-1} Z_t' + H_t' \big)^{-1} Z_t \mathbf{\Sigma}_{t|t-1} T_t' + R_t Q_t R_t' \end{split}$$

Linear Gaussian State Space Model

notation

	Tsay	KFAS
state	s_t	α_t
conditional mean for state	$s_{t t-1}$	\boldsymbol{a}_t
smoothed state	$s_{t T}$	$\hat{\boldsymbol{\alpha}}_t$
conditional variance of state	$\mathbf{\Sigma}_{t t-1}$	\boldsymbol{P}_t
variance of smoothed state	$\mathbf{\Sigma}_{t T}$	\boldsymbol{V}_t
variance of forecast error	V _t	\boldsymbol{F}_t
sample size	Т	n
measurements	${m y}_t$ is $k{ imes}1$ vector	\mathbf{y}_t is $p \times 1$ vector
state	\boldsymbol{s}_t is $m \times 1$ vector	$lpha_t$ is $m{ imes}1$ vector
transition equation innovation	$oldsymbol{\eta}_t$ is $n{ imes}1$ vector	$oldsymbol{\eta}_t$ is $k{ imes}1$ vector

- state-space model framework allows to easily estimate models with time varying parameters
- consider for example a capital asset pricing model with with time-varying intercept and slope

$$\begin{aligned} r_t &= \alpha_t + \beta_t r_{M,t} + \varepsilon_t & \varepsilon_t \sim \textit{N}(0, \sigma_\varepsilon^2) \\ \alpha_{t+1} &= \alpha_t + \zeta_t & \zeta_t \sim \textit{N}(0, \sigma_\zeta^2) \\ \beta_{t+1} &= \beta_t + \eta_t & \eta_t \sim \textit{N}(0, \sigma_\eta^2) \end{aligned}$$

where r_t is excess return of an asset, and $r_{M,t}$ is excess return of the market

▶ to obtain state-space representation rewrite above model in matrix form

$$r_{t} = \begin{bmatrix} 1 & r_{M,t} \end{bmatrix} \begin{bmatrix} \alpha_{t} \\ \beta_{t} \end{bmatrix} + \varepsilon_{t} \qquad \qquad \varepsilon_{t} \sim N(0, \sigma_{\varepsilon}^{2})$$

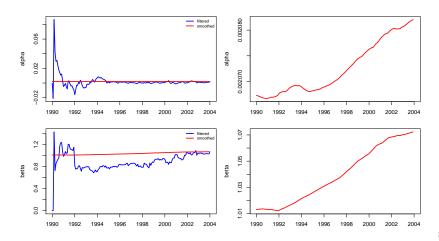

$$\begin{bmatrix} \alpha_{t+1} \\ \beta_{t+1} \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} \alpha_{t} \\ \beta_{t} \end{bmatrix} + \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} \zeta_{t} \\ \eta_{t} \end{bmatrix} \qquad \begin{bmatrix} \zeta_{t} \\ \eta_{t} \end{bmatrix} \sim N \begin{pmatrix} \begin{bmatrix} 0 \\ 0 \end{bmatrix}, \begin{bmatrix} \sigma_{\zeta}^{2} & 0 \\ 0 & \sigma_{\eta}^{2} \end{bmatrix} \rangle$$

and let $\mathbf{y}_t = r_t$, $\mathbf{s}_t = (\alpha_t, \beta_t)'$, $\mathbf{T}_t = \mathbf{R}_t = \mathbf{I}_2$, $\mathbf{Z}_t = [1, r_{M,t}]$, $\mathbf{H}_t = \sigma_{\varepsilon}^2$, $\mathbf{Q}_t = \text{diag}\{\sigma_{\zeta}^2, \sigma_{\eta}^2\}$

```
# load data on excess returns from January 1990 to December 2003
# http://faculty.chicagobooth.edu/ruey.tsay/teaching/fts3/m-excess-c10sp-9003.txt

legend("topright", c("filtered", "smoothed"), col=c("blue", "red"), lwd=2, cex=0.7, bty="n")

# plot smoothed state alpha and betta
plot.ts(alpha.KFS[,2], plot.type="single", xlab="",ylab="alpha", col="red", lwd=2)
plot.ts(betta.KFS[,2], plot.type="single", xlab="",ylab="betta", col="red", lwd=2)
```

▶ note that smoothed states $\alpha_{t|T}$ and $\beta_{t|T}$ are much smoother than filtered state $\alpha_{t|t-1}$ and $\beta_{t|t-1}$, since Kalman smoothing uses information from the whole sample, but Kalman filtering only information up to period t

Unobserved Components Model

 goal: decomposition of time series into trend, seasonal and irregular component

$$y_t = \mu_t + \gamma_t + \varepsilon_t$$

where

 v_t is the observed data

 μ_t is an slowly changing component (trend)

 γ_t is periodic seasonal component

 ε_t is irregular disturbance component

and μ_t , γ_t , ε_t are modeled explicitly as stochastic processes

- ightharpoonup note that local level model and local linear trend model are special cases of the unobserved components model with no seasonal component γ_t
- seasonal component can be modeled using time varying dummy variables as

$$(1+B+\ldots+B^{s-1})\gamma_{t+1}=\omega_t \qquad \omega_t \sim N(0,\sigma_\omega^2)$$

so that in expectation the sum of the seasonal effects captured by dummy variables $\gamma_t, \gamma_{t-1}, \ldots, \gamma_{t-s+1}$ is zero

▶ local linear trend model with seasonal component

$$y_{t} = \mu_{t} + \gamma_{t} + \varepsilon_{t} \qquad \qquad \varepsilon_{t} \sim N(0, \sigma_{\varepsilon}^{2})$$

$$\mu_{t+1} = \beta_{t} + \mu_{t} + \zeta_{t} \qquad \qquad \zeta_{t} \sim N(0, \sigma_{\zeta}^{2})$$

$$\beta_{t+1} = \beta_{t} + \eta_{t} \qquad \qquad \eta_{t} \sim N(0, \sigma_{\eta}^{2})$$

$$(1+B+B^{2}+B^{3})\gamma_{t+1} = \omega_{t} \qquad \qquad \omega_{t} \sim N(0, \sigma_{\omega}^{2})$$

lacktriangle seasonal dummy approach: $\gamma_{t+1} = -\sum_{j=0}^2 \gamma_{t-j} + \omega_t$

▶ to obtain state-space representation rewrite the above model in matrix form

$$y_t = \begin{bmatrix} 1 & 0 & 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} \mu_t \\ \beta_t \\ \gamma_t \\ \gamma_{t-1} \\ \gamma_{t-2} \end{bmatrix} + \varepsilon_t$$

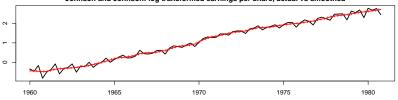

$$\underbrace{Z_t} \underbrace{S_t} \underbrace{S_t} \underbrace{\varepsilon_t}$$

$$\underbrace{\begin{bmatrix} \mu_{t+1} \\ \beta_{t+1} \\ \gamma_{t+1} \\ \gamma_t \\ \gamma_{t-1} \end{bmatrix}}_{S_{t+1}} = \underbrace{\begin{bmatrix} 1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & -1 & -1 & -1 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix}}_{T_t} \underbrace{\begin{bmatrix} \mu_t \\ \beta_t \\ \gamma_t \\ \gamma_{t-1} \\ \gamma_{t-1} \end{bmatrix}}_{S_t} + \underbrace{\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix}}_{R_t} \underbrace{\begin{bmatrix} \zeta_t \\ \eta_t \\ \omega_t \end{bmatrix}}_{T_t}$$

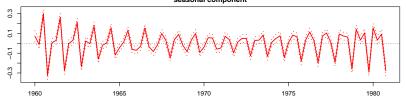

where

$$\begin{split} \varepsilon_t &\sim \textit{N}(0, \underbrace{\sigma_\varepsilon^2}_{\textit{H}_t}) \\ \begin{bmatrix} \zeta_t \\ \eta_t \\ \omega_t \end{bmatrix} &\sim \textit{N} \left(\begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}, \underbrace{\begin{bmatrix} \sigma_\zeta^2 & 0 & 0 \\ 0 & \sigma_\eta^2 & 0 \\ 0 & 0 & \sigma_\omega^2 \end{bmatrix}}_{\textit{\textbf{Q}}_t} \right) \end{split}$$

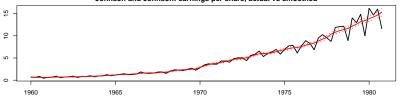

Johnson and Johnson: log transformed earnings per share, actual vs smoothed

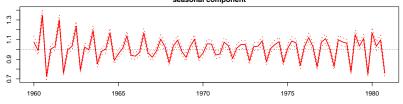

seasonal component

Johnson and Johnson: earnings per share, actual vs smoothed

seasonal component

Missing Values

Kalman Filtering and Smoothing can easily deal with missing data

case 1:

- b observations for all variables in y are missing for some periods
- thus no new information available at these time points; Kalman filtering and smoothing procedures remains same but with

$$v_t = 0$$
 $K_t = 0$

for periods with missing values

case 2:

- ightharpoonup some components of y are missing for some periods
- ▶ let $y_t^* = Jy_t$ be the vector of observed data, where J_t are the rows of $k \times k$ identity matrix corresponding to observed variables
- Kalman filtering and smoothing procedure remain same, but observation equation for periods with missing data is replaced with

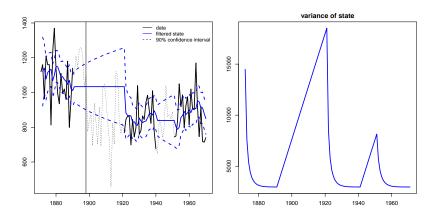

$$\boldsymbol{y}_t^* = \boldsymbol{c}_t^* + \boldsymbol{Z}_t^* \boldsymbol{s}_t + \boldsymbol{\varepsilon}_t^*$$

where $c_t^* = Jc_t$, $Z_t^* = JZ_t$, $\varepsilon_t^* = J\varepsilon_t$ and $H_t^* = JH_tJ'$

Application: Local Level Model for Nile Data with Missing Values

```
# annual flow of the river Nile at Ashwan 1871-1970
v.ts <- datasets::Nile
# create missing values
v.ts[21:50] <- NA
v.ts[71:80] <- NA
# define the state-space local level model
y.LLM <- SSModel(y.ts ~ SSMtrend(1, Q = list(NA)), H = NA)
# maximum likelihood estimation of paramaters of Q and H
initvals <- rep(var(y.ts, na.rm = TRUE), 2)/10000
y.LLM.ML <- fitSSM(model = y.LLM, inits = initvals, method = "BFGS")
# Kalman filtering and smoothing
v.KFS <- KFS(v.LLM.ML$model)
# confidence intervals for filtered and smoothed state
y.KF <- predict(y.LLM.ML$model, interval = "confidence", level = 0.9, filtered = TRUE)
v.KS <- predict(v.LLM.ML$model, interval = "confidence", level = 0.9)
# replace filtered state for first period by NA
v.KF[1,] <- NA
```

Application: Local Level Model for Nile Data with Missing Values

Application: Local Level Model for Nile Data with Missing Values

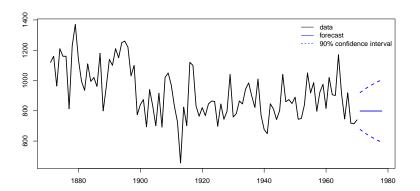

- ▶ local level model implies that the filtered state $y_{t|t-1}$ remains constant during the period where no additional information is obtained due to missing values
- the variance of the filtered state is increasing and confidence intervals are getting larger during the period with missing observations
- the error can thus be quite large if a structural break occurs during the period with missing data, due to an event like here the construction of dam in 1898

Forecasting with State Space Models

- essentially identical to having missing observations at the end of the sample
- usual Kalman filter recursion is thus performed, but on an extended sample with missing observations added at the end of the sample (number of missing observations added is the same as the desired forecast horizon)

Application: Local Level Model for Nile Data

```
# forecast horizon
h <- 8
# create forecast
y.fcst <- predict(y.LLT.ML$model, interval = "confidence", level = 0.9, n.ahead = h, filtered = TRUE)
# plot the forecast
cols <- c(1,4,4,4)
ltys <- c(1,1,2,2)
cbind(y.ts, y.fcst) %%
